Understand Photoshop's primary image editing commands One of the most important aspects of learning to edit with Photoshop is to understand the primary commands and how to use them. These tools are fundamental to the way Photoshop edits raster images. They are some of the most common user tasks. A large portion of the Photoshop training manuals focus on getting you up to speed with the primary command sets. To

help you determine how well you've learned the tools and understand what you've practiced, you can take the Image Editing Quiz at `www.digitalphotographysecrets.com/image-editing-quiz.html`. The quiz helps determine how much you really know about Photoshop's image editing commands, thus helping you assess how much you need to learn about the subject. In this section, I briefly outline Photoshop's primary image editing commands. In the previous

chapters, I discussed how to use Photoshop to crop, correct, and straighten images. I also discussed basic keyboard shortcuts. * Crop: Crop is the act of reducing the size of an image, either by narrowing the size or slicing parts off the edges. This is done in Photoshop by selecting the crop tool or pressing the C key. In the Crop menu, shown in Figure 5-12, all five crop tools are available. The Crop mode tool is the one that enables you to limit the view to the cropped area. In Crop mode, the

Crop tool actually crops out the background part of the image. However, you can only crop one layer at a time. The entire crop tool looks like the one shown in Figure 5-12. Click the view mode tool in the toolbox and choose Crop from the menu that appears. Click the crop tool in the Toolbox. You can also select the crop tool from the Tools panel, as shown in Figure 5-13, and then click and drag in the image. Note that you can select the crop tool and drag in the image, but if you resize the image using the

Crop tool's rectangle, only that area will be cropped. FIGURE 5-12: You have five crop tools available in the Crop menu. * The smaller arrows in the upper-right corners of the Crop Tools toolbox menu, as shown in Figure 5-12, enable you to modify the crop window to make the cropped area smaller or larger. Note that when you select the crop tools, the view is cropped to the area that you want to

Habitat configuration, species-specific density and the distribution of birds in the Grenadines Islands, Caribbean. The number of birds in a protected area is generally influenced by a variety of attributes and may therefore differ from that predicted from a random sampling of all sites. Such differences may reflect variations in habitat use by a species or local selection by individuals. Data for five species of birds were collected

in a patch-matrix design and a random-plot survey at two sites in the western and southern parts of St. Lucia. For each species there was a significant difference in the mean number of individual birds recorded in a random-plot survey from the mean number estimated using a patch-matrix. The pattern of individual variation in numbers of birds recorded at random plots was similar for all the species surveyed. Also, for all species, birds were more abundant in unhabitat patches than in patches

with habitat. The density of birds within habitat patches was, for all species, significantly and positively related to the abundance of the habitat component, the extent of habitat patch and the abundance of conspecifics, but not the abundance of heterospecifics. Because species were surveyed at two similar sites in very different habitats, our results are consistent with the species being territorial and the habitat a limiting factor in determining patch use by individuals. Our results also suggest

that habitat quality is a better predictor of abundance than is the magnitude of population density.Q: Sortable drag and drop reordering icons in a list I have a list of icons that is sortable using jQuery drag and drop. Draggable Reorderable Sortable Icon Checkable Checkbox

Acetylcholinesterase activity in the nervous system of the earthworm, Eisenia fetida. In the nervous systems of insects

acetylcholinesterase (AChE) exhibits its maximal activity in both cell bodies and nerve fibres. In an effort to establish a baseline for the study of acetylcholinesterase in the nervous system of a soil-dwelling nematode, this enzyme was studied in the central and peripheral nervous systems of the earthworm, Eisenia fetida. AChE was localized in the ciliated brain ganglia and ventral nerve cords. Cell bodies in the brain and ventral nerve cords as well as motor and sensory neurones

were found to contain the enzyme. Maximal enzyme activity was found in the medial and peripheral nerve tracts of the ventral nerve cords, with lesser activity in the lateral tracts. In the ventral nerve cord, both the enzyme activity in the brain and the ventral nerve cords and the different types of AChE-immunoreactive fibres were sensitive to the electric organ blocker pentylenetetrazol. About 3% of the cells in the brain and ventral nerve cords and 4% of the neurones in the nervous system

were immunoreactive for AChE. Ask HN: Has anyone found jobs/funding by selling an app? - parkaboy Hey, I'm currently working on my app (http://parkability.com/). We've already started taking the first steps towards building it and I'm curious how others have found gigs/funding. Any input would be helpful. ====== JSeymourATL Ask them to share their strategies. This is fairly competitive. ---

abstract: 'Entity typing is the task of identifying entities and their

types in text. Previous works have mainly focused on either entity extraction or entity typing. We present DeepPointer, a neural approach to combine both tasks, where a single neural network jointly models entity extraction and entity typing. In DeepPointer, entities are first identified using Named Entity Recognition (NER) models, which are trained on data using weak annotations of entity and type information. These identified entities are then used as object tokens in the deep Pointer
